Deployment strategy and Features

Instructions

Building containers

1. Typescript microservices should be building using multilayer building approachment.
2. This is necessary to avoid problems with caching dependencies, lightness of the container and hiding the source code. The following is a three-tier build template
3. Three-layer construction makes the container lighter and does not include development dependencies in the final image
4. Creating your own user and group isolates the application from executing root commands and escalating privileges
5. Using node:12-alpine gives the stability of Node.js version 12 and the lightness of the Alpine image
